### Abstract

In earlier work structure-based design studies resulted in the discovery of alkyl substituted diphenyl ether inhibitors of InhA, the enoyl reductase from *Mycobacterium tuberculosis*. Compounds such as 5-hexyl-2-phenoxyphenol **19** are nM inhibitors of InhA and inhibit the growth of both sensitive and isoniazid-resistant strains of *Mycobacterium tuberculosis* with MIC<sub>90</sub> values of 1–2 µg/mL.

However, despite their promising *in vitro* activity, these compounds have ClogP values of over 5. In efforts to reduce the lipophilicity of the compounds, and enhance potentially enhance compound bioavailability, a series of B ring analogues of **19** were synthesized that contained either heterocyclic nitrogen rings or phenyl rings having amino, nitro, amide or piperazine functions. Compounds **3c**, **3e** and **14a** show comparable MIC<sub>90</sub> values to that of **19**, but have improved ClogP values.

### Keywords

Tuberculosis; Diaryl ether; enoyl reductase; mycolic acids; InhA; isoniazid

Tuberculosis (TB) is responsible for more than 1.6 million deaths per annum with 8.8 million new cases being reported each year. These numbers make TB one of the leading infectious causes of death, eclipsed only by AIDS. In addition, according to the World Health Organization, the number of multi-drug-resistant and extensively drug-resistant TB cases is growing with almost a half million new cases being reported each year. Therefore, there is an urgent need to develop novel TB chemotherapeutic agents.<sup>1</sup>

**Publisher's Disclaimer:** This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final citable form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

The current front-line treatment strategy utilizes isoniazid (INH), a pro-drug which inhibits the synthesis of mycolic acids that are essential components required for the integrity of the bacterial cell wall.<sup>2</sup> INH inhibits InhA, the FabI enoyl reductase (ENR) in the fatty acid synthesis (FAS-II) pathway. However, before INH can inhibit InhA, it must be activated by KatG, a catalase-peroxidase enzyme. The activated form of INH then reacts with NAD<sup>+</sup> to form the INH-NAD adduct (Scheme 1).<sup>3–7</sup> A significant number of the strains resistant to INH arise from mutations in KatG.<sup>8–11</sup> Therefore, the development of an InhA inhibitor which can by-pass this initial activation step should have activity against INH-resistant strains of *Mycobacterium tuberculosis* (MTB).

The diphenyl ether triclosan (Scheme 1) is a potent inhibitor of ENR's from many organisms including *Escherichia coli* and *Plasmodium falciparum*.<sup>12–20</sup> However this compound only inhibits InhA with a K<sub>i</sub> value of 0.2 μM.<sup>21</sup> Using structure-based drug design we developed a series of alkyl diphenyl ethers that are potent inhibitors of InhA, with K<sub>i</sub> values as low as 1 nM and MIC<sub>90</sub> values of 1–2 μg/mL against *M. tuberculosis* H37<sub>Rv</sub>.<sup>22</sup> Importantly the alkyl diphenyl ethers display similar MIC values against INH-resistant strains of MTB.<sup>22</sup> However, despite their promising *in vitro* activity, these compounds have relatively low solubility and have ClogP values greater than 5, which is likely one reason why they have limited *in vivo* efficacy.<sup>23</sup> Based on the observed relationship between lipophilicity and *in vivo* efficacy, especially as it pertains to antibacterial compounds,<sup>24, 25</sup> we synthesized a series of analogues that incorporated functionalities designed to increase the polarity of the parent diphenyl ether InhA inhibitors. The effect on compound polarity was estimated by calculating the logP value (ClogP) for each compound synthesized.

In this study we describe two classes of molecules in which alterations have been made to the diphenyl ether 'B' ring. In one series of compounds we have replaced the B ring with isosteric heterocycles that incorporate nitrogen atoms within the ring, thereby causing little steric perturbation to the overall structure of the molecule (Scheme 2). The second series of compounds have nitro, amino, amide and piperazino functionalities incorporated at the *ortho*, *meta*, or *para* positions of the B ring (Scheme 3 and Scheme 4). This second series of compounds was synthesized not only to improve solubility but also to systematically identify positions on the B ring which could be substituted without diminishing biological activity.

The synthesis of the heterocyclic diaryl ether compounds was initiated either by nucleophilic aromatic substitution or by Buchwald-Hartwig cross-coupling of the appropriate nitrogen heterocycle with 4-bromo or chloro-2-methoxy phenol producing **1a–f** (Scheme 2).<sup>26, 27</sup> This was followed by palladium catalyzed Negishi coupling of the diaryl ethers with hexyl zinc chloride to give **2a–f**.<sup>28</sup> Boron tribromide cleavage of the methyl ether was used subsequently to generate the respective phenols, **3a–f**.<sup>29</sup> Structural characterization of all compounds was performed using <sup>1</sup>H NMR and ESI/MS.

The synthesis of the nitro, amino and amide-substituted compounds was performed using the series of reactions shown in Scheme 3. Nucleophilic aromatic substitution reactions with fluoronitrobenzenes were first used to generate compounds **4a–c**.<sup>27</sup> This was followed by Negishi coupling giving **5a–c** followed by boron tribromide cleavage to give compounds **13a–c** or zinc-mediated reduction giving anilines **6a–c**.<sup>28–30</sup> Cleavage of the methyl ether gave **14a–c** while acylation of the anilines with acyl chlorides afforded compounds **7, 8** and **9a–c**.<sup>29, 31</sup> Boron tribromide cleavage then gave the final compounds **10, 11** and **12a–c**.<sup>29</sup>

The piperazine derivatives were synthesized in a similar fashion starting with nucleophilic aromatic substitution with the 2- or 4-fluorobenzaldehyde to give **13a** and **b** (Scheme 4).<sup>27</sup> Subsequently, reductive amination with methyl piperazine and sodium triacetoxyborohydride

produced **14a** and **b**,<sup>32</sup> whereas Negishi coupling followed by boron tribromide cleavage gave the final compounds **16a** and **b**.<sup>28, 29</sup>

The *in vitro* activities of the ultimate products were evaluated using enzyme inhibition and whole cell antibacterial assays as described previously (Table 1–Table 3).<sup>22, 33, 34</sup> In general, addition of a bulky substituent at either the *ortho*, *meta* or *para* position of the B ring of **19** or incorporation of most aromatic nitrogen heterocycles resulted in a significant reduction in both enzyme inhibition and antibacterial activity (Table 1 and Table 3). In contrast, introduction of either amino or nitro substituents at the *ortho* and *para* positions had only a minimal effect on activity (Table 2). The two most active compounds, **3c** and **14a**, have MIC<sub>90</sub> values of 3.13 µg/mL, similar to that of **19**, and have ClogP values of 4.97 and 5.24, respectively, compared to 6.47 for the parent compound (Table 1 and Table 2). In addition it is also worth noting that the pyrazine derivative **3e**, has a ClogP value that is more than an order of magnitude lower than **19**, but still only shows a 3-fold increase in MIC<sub>90</sub> compared to the parent (Table 1). In general the MIC values correlated with the IC<sub>50</sub> values for enzyme inhibition. Thus *ortho* and *para* amino substituents (**14a,c**) were well tolerated in addition to the *meta* nitro substituent (**13b**). In these three cases the IC<sub>50</sub> values obtained using 100 nM InhA approached 50% of the enzyme concentration, indicating that these compounds are tight-binding enzyme inhibitors. Additional IC<sub>50</sub> values were determined using 10 and 50 nM InhA in the enzyme assays. Subsequent linear regression analyses of the IC<sub>50</sub> values as a function of enzyme concentration yielded estimates for K<sub>i</sub><sup>app</sup> of 21 ± 3 nM (**13b**), 16 ± 12 nM (**14a**) and 40 ± 3 nM (**14c**). Thus, introduction of a *meta* nitro (**13b**) or an *ortho* amino (**14a**) group into the B ring of the parent compound **19** has only a minor effect on the affinity of the inhibitor for the enzyme. Compound **14a** is of particular interest because this derivative has a MIC<sub>90</sub> value that is close to the value determined for **19**. These data provide important information on the structural flexibility of the inhibitor binding-site that will be useful in directing the design of additional compounds.

In conclusion, a series of hexyl diaryl ethers were synthesized in which the B ring of compound **19** has been substituted with a variety of groups, or replaced with nitrogen-containing aromatic heterocycles. Several of these new compounds possess MIC<sub>90</sub> and K<sub>i</sub><sup>app</sup> values similar to that of **19** while having significantly improved ClogP values. Studies are currently underway to determine whether the modifications that we have introduced have resulted in an increase in compound bioavailability and an improvement in their *in vivo* antibacterial activity.
